- State management is up to you

Assignment

Write a "widget" to select 3 elements from a list. As test data, an arbitrary number of elements with sequence numbers will be suitable - ["Element 1", "Element 2", "Element 3", ...].

Logical conditions:

- A list of already selected items is displayed (no more than three).
- By clicking on the "Change my choice" button, a section opens with a list of all elements (a scrollable list of fixed height), as well as a search field and filter.
- Checkboxes of already selected items are checked, and the selected items are duplicated as blocks at the bottom of the section.
- Search: as you type characters, the list of elements is filtered (using substring search).
- Additional filter (selectbox) - filter by element number (>100, >2500, >10000). Search and filter complement each other.
- You can select no more than three items, in case three items are selected, the remaining checkboxes become disabled.
- The selected items have an "x" which removes the item from the list of selected items.
- Clicking on the "Save" button closes the section and the list of selected items on the main page is updated.
- When you click on the "Cancel" button, the section closes and the list of selected items on the main page remains unchanged.

Below is an example of how the "widget" could look. The focus is on functionality.

Select items

You currently have 2 selected items.

Element 5 | x

Element 51 | x
